

The Complexity Class P (continued)

Alan Cobham [1964], Jack Edmonds [1965], and Michael Rabin [1966] suggested the “**polynomial time**” as a broad classification of problems that are solvable in a *reasonable amount of time*

$$P = \bigcup_{k>0} \text{TIME}(n^k)$$

Why polynomial, why not, say n^3 ?

Because the “polynomial time” is invariant under the model of computation

NP is the **nondeterministic counterpart of P**

$$\text{NP} = \bigcup_{k>0} \text{NTIME}(n^k)$$

Classes P and NP

Problems in P

The Path Problem

Input: A directed graph $G = (V, E)$ and $s, t, 1 \leq s, t \leq |V|$

Question: Does the graph has a directed path from s to t ?

PATH : the set of all positive instances $\langle G, s, t \rangle$ to the Path Problem

An encoding of a graph can be its **adjacency matrix** (a_{ij}) :

for every $i, j, 1 \leq i, j \leq n, a_{ij} = 1$ if $(i, j) \in E$ and 0 otherwise

The entire encoding can be

$$0^n \# a_1 a_2 \dots a_n \# 0^s \# 1^t,$$

where a_1, a_2, \dots, a_n are the rows of the adjacency matrix

The Complexity Class P

Juris Hartmanis and Dick Stearns [1965] : proposed *computational complexity* — measuring complexity of problems by the number of steps (or the number of cells) expended in the worst case under the TM model

Fundamental results in the Hartmanis-Stearns paper:

1. **Time Hierarchy Theorem** (see Section 9.1) . . .

$$\text{TIME}(t(n)) \neq \text{TIME}(t(n)^2) \text{ for all reasonable } t(n)$$

2. **Linear Speed-up Theorem** . . .

$$\text{TIME}(t(n)) = \text{TIME}(ct(n)) \text{ for all } c > 0 \text{ and all reasonable } t(n)$$

A better hierarchy theorem is proven by Harry Lewis and Stearns

A Polynomial Time Algorithm for RELPRIME

Use the Euclidean Algorithm: On input $\langle x, y \rangle$:

1. **repeat** $x \leftarrow x \bmod y$; swap x and y ; **until** $y = 0$
2. **output** x

How quickly does x decrease?

If $y > x/2$, then $x \bmod y \leq x - y < x/2$;

If $y \leq x/2$, then $x \bmod y \leq y - 1 < x/2$.

So, each iteration reduces x by at least half.

if $\max\{|x|, |y|\} = n$, then the running time is $O(n^3)$.

(*) if the Euclidean on $\langle x, y \rangle$ outputs 1 **then accept** ; **else reject**

The Running Time Analysis: $O(n^3)$.

A Polynomial Time Algorithm for PATH

Let $G = (V, E)$ be an instance of PATH, $n = |V|$, and A the adjacency matrix of G .

For each $k \geq 1$, let $A^{(k)}$ be the k th power of A , where \vee and \wedge replace $+$ and \times .

Then for every $k \geq 1$ and every $i, j, 1 \leq i, j \leq n$, **the (i, j) th entry of $A^{(k)}$ is a 1 if and only if there is a directed path from i to j of length at most k in G .**

Thus the following will do:

(*) Compute $B = A^{(n)}$; if the (s, t) th entry of $B = 1$ **accept** ; **else reject**

The Running Time Analysis: $2n$ bits examined per entry, n^2 entries, $n - 1$ sequential multiplication yields $A^{(n)} \dots$ an $O(n^4)$ step algorithm

Polynomial Time Decidability of Context-Free Languages

Theorem. *Every context-free language is in P.*

Proof Let L be context-free. Let G be a CNF grammar for L . Suppose $w = w_1 \dots w_n$ be a string whose membership in L we are testing

if $n = 0$ **then accept** if and only if $S \rightarrow \epsilon$ is rule.

For each $i, j, 1 \leq i \leq j \leq n$, let $t(i, j)$ be the set of all variables from which $w_i \dots w_j$ can be produced

Idea: Compute $t(i, j)$ for all $i, j, 1 \leq i \leq j \leq n$, using **dynamic programming**; then test the membership by examining whether $S \in t(1, n)$

Testing Relative Primality of Two Numbers

The Relative Primality Problem

Input: Integers $x, y \geq 1$

Question: Are x and y , relatively prime, i.e., $\gcd(x, y) = 1$?

RELPRIME : the set of all positive instances $\langle x, y \rangle$ of the Relative Primality Problem

Note: x and y should not be encoded in unary

A Characterization of NP by Verifiers

A **verifier** of a language A is an algorithm V such that $A = \{w \mid V \text{ accepts } \langle w, c \rangle \text{ for some } c\}$.

Measure the time of V in terms of the length of w . For a fixed V , the string c witnessing to $\langle w, c \rangle \in A$ is called a **certificate** or a **proof**

Definition. (alternate) NP is the class of languages that have polynomial time verifiers.

Equivalence Between the Two Definitions of NP

Theorem. The alternative definition is equivalent to the first definition of NP.

Proof (Sketch) Let p be any polynomial.

Suppose L has a $p(n)$ time verifier V . Then for every x , we can consider all certificates of length at most $p(|x|)$. Let N be an NTM that, on input x , (i) nondeterministically guess a string c , $|c| \leq p(n)$, (ii) simulates V on $\langle x, c \rangle$, and (iii) accepts if and only if V has accepted. Then N decides L and is $O(p(n))$ time.

Suppose L is decided by a $p(n)$ time NTM N . Consider a verifier V that, on input $\langle x, c \rangle$, simulates N on x along c for at most $p(|x|)$ steps and accepts if and only if N has accepted., tests whether c encodes Then for every x , V accepts x for some c if and only if N on x accepts for some computation path. ■

Dynamic Programming for Computing the Table

Initial: $t(i, i) \leftarrow$ the set of all A such that $A \rightarrow w_i$ is a rule

Loop:

```
for  $\ell = 2$  to  $n$ 
  for  $i = 1$  to  $n - \ell + 1$ 
     $j = i + \ell - 1$ ;  $t(i, j) = \emptyset$ ;
    for  $k = i$  to  $j - 1$ 
      if  $\exists A, B \in t(i, k), C \in t(k + 1, j)$  such that  $A \rightarrow BC$  is a rule
        then add  $A$  to  $t(i, j)$ 
```

Final Test: accept if and only if $S \in t(1, n)$ ■

The Class NP

The Hamilton Path Problem

Input: A directed graph $G = (V, E)$ and $s, t \in V, s \neq t$

Question: Is there a Hamilton Path from s to t in G , i.e., a directed path from s to t that visits all the nodes exactly once?

HAMPATH : the set of all positive instances $\langle G, s, t \rangle$ to the Hamilton Path Problem

The Compositeness Problem

Input: Integer $x \geq 1$

Question: Does x a composite number, i.e., have an integer divisor other than 1 and x ?

COMPOSITES : the set of all composite numbers x

More Problems in NP (cont'd)

The Subset Sum Problem

Input: integers x_1, \dots, x_k and t

Question: Is there a subset of $\{x_1, \dots, x_k\}$ that adds up to t ?

SUBSET-SUM : the set of all positive instances $\langle S, t \rangle$ to the Subset Sum Problem

Theorem. *SUBSET-SUM is in NP.*

Proof (Sketch) Define a certificate for an instance $\langle S, t \rangle$ with $|S| = n$ in *SUBSET-SUM* to be an n bit sequence such that $\sum_{i=1}^n c_i x_i = t$

Then verification can be done in $O(n^2)$ steps. ■

Membership of HAMPATH and COMPOSITES in NP

HAMPATH: Define a certificate for each $\langle G, s, t \rangle \in \text{HAMPATH}$ to be any sequence $\langle v_1, \dots, v_n \rangle$ of nodes such that

(i) for every i , $1 \leq i \leq n$, $i = v_j$ for some j ,

(ii) $s = v_1$,

(iii) $t = v_n$, and

(iv) for every i , $1 \leq i \leq n - 1$, $(v_i, v_{i+1}) \in E$.

A correct certificate can be of length $O(n \log n)$ and verification can be done in $O(n^3)$ steps.

COMPOSITES: Define a certificate for each $x \in \text{COMPOSITES}$ to be any number y such that y divides x and $1 < y < x$. Then a correct certificate can be of length $O(n)$

More Problems in NP

The Clique Problem

Input: A graph $G = (V, E)$ and $k \geq 1$

Question: Does G contain a complete graph of size $\geq k$?

CLIQUE : the set of all positive instances $\langle G, k \rangle$ to the Clique Problem

Theorem. *CLIQUE is in NP.*

Proof (Sketch) Define a certificate for an instance $\langle G, k \rangle$, where G is an n node graph, to be an n bit sequence $c = c_1 \dots c_n$ such that:
for every i, j , $1 \leq i < j \leq n$, if $c_i = c_j = 1$, then $(i, j) \in E$

Then verification can be done in $O(n^3)$ steps. ■
